

Three strategies, three signatures: what the printed equations cannot separate and this model can

One parameter set, one mechanism changed at a time: resistance = $EC_{50} \times 16$; tolerance = replication and both kill rates /4 together, which is what leaves the MIC exactly invariant; persistence = dormancy entry $\times 10$. In C and D each strain is exposed to 8x its own MIC, removing the trivial effect that a resistant strain survives a dose chosen for a susceptible one.
