

Sensitivity analysis: the published ranking is an identity of the equation, not a property of the bacteria

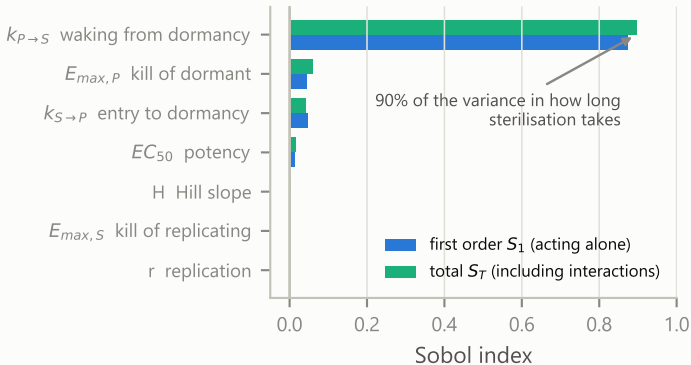

A method as published: OAT on the printed Eq. 4
M. tuberculosis, log₁₀ drop at 240 h

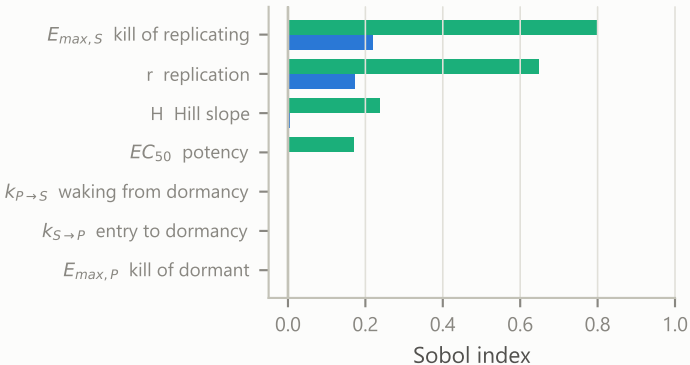

B the same OAT on the mechanistic model
M. tuberculosis, time to sterilisation

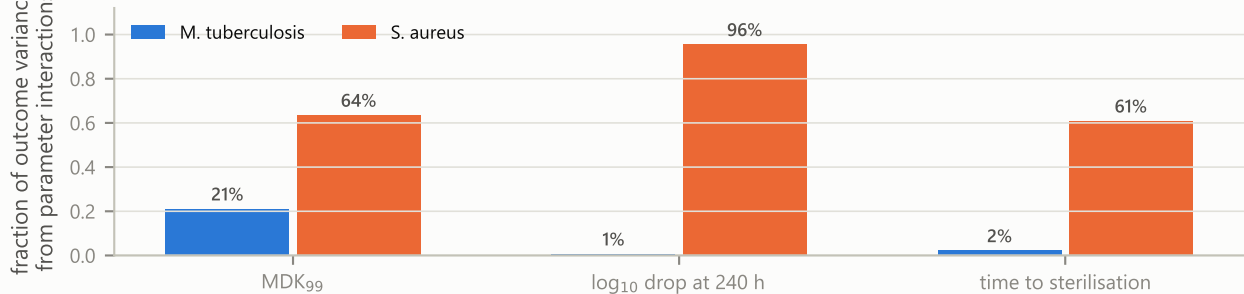

C *M. tuberculosis*, time to sterilisation

D *S. aureus*, time to sterilisation

E what one-at-a-time analysis cannot see

A and B vary one parameter at a time by +/-10%, exactly as Methods 2.3.2 describes. C and D use 4,608 model

evaluations per species (Saltelli estimator, 512 base samples, parameters log-uniform over +/-50%).

Where the bars in E are tall, no one-at-a-time analysis can be trusted, however carefully it is run.
