

A

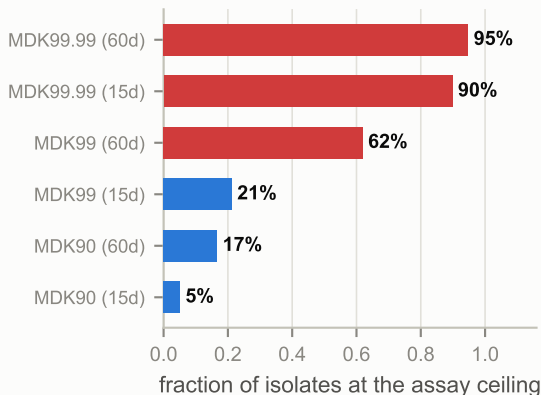

All 24 comparisons the file supports, against the correction each must beat

Amber: the 4 results reaching nominal significance, where 1.2 are expected by chance. Every one of them lies to the right of the critical value it would have to beat, so none survives. All four are negative, the direction a shared mechanism does not predict.

B

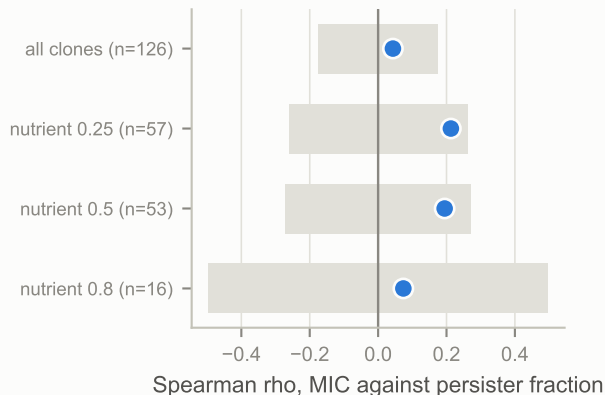

The deepest endpoint is mostly censored

Red where more than half the isolates never reached the target within the six-day assay. The four nominal results in panel A concentrate here.

C

126 evolved clones, one ancestor

Grey band: the correlation each stratum could have resolved at 95% confidence. Every estimate falls inside its own band, so the null is bounded rather than asserted.
