

A A rate is estimable in all six

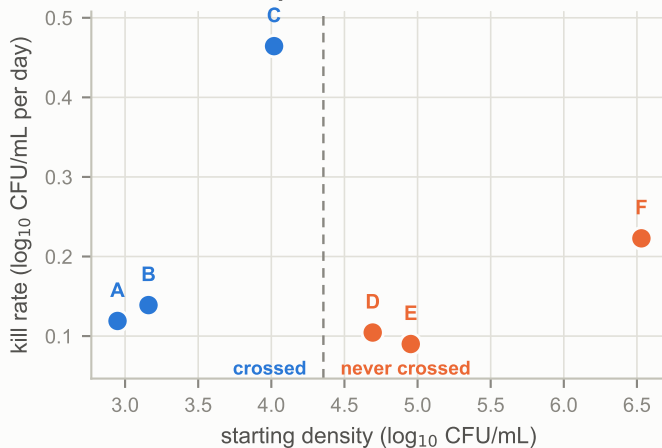

MXF 10x MIC. Bars are 95% profile-likelihood intervals from the censored (Tobit) fit. Blue: laboratory with a flask ever below the floor at the 100 uL plating; orange: never, in any arm.

B A duration is undefined in three

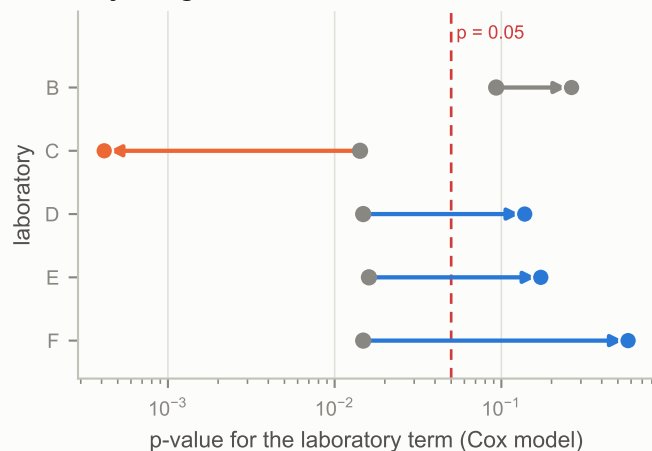

Kaplan-Meier, all treated flasks, 100 uL plating. Three curves never descend: those laboratories recorded no flask below the floor in any arm, so no crossing time exists.

C The inoculum splits them; the rate does not

The three lowest starting densities are exactly the three laboratories that crossed at the 100 uL plating. F kills faster than four of the other five and never crosses.

D Adjusting for the inoculum absorbs three of four

Grey: laboratory alone. Arrow head: after adding starting density. Blue crosses from significant to not. Orange (C) stays significant and also has the fastest rate.
